This is a closed book exam.	
This is a closed book exam.	
Write clearly and justify your answers.	

Time limit: 105 min.

Question:	1	2	3	4	5	Total
Points:	20	20	20	20	20	100
Score:						

- 1. Consider the absolute loss function for the discrete case  $l(p,y) = \sum_{i=1}^{C} |p_i y_i|$ . C is the number of class values,  $p = [p_1, \dots, p_C]$  is the predicted probability distribution of class values and  $y = [y_i, \dots, y_C]$  is the outcome, where all  $y_i$  except one are zero. Use  $r = [r_1, \dots, r_C]$  as the true distribution of the data generative process.
- [10] (a) This is an improper scoring rule. Explain what this means and describe other types of scoring rules.
- [10] (b) Which distribution minimizes the risk with this loss function? Take into account multiple class values C (not just 2). Prove your answer.

$$M = [0,7, 0.1, 0.2]$$

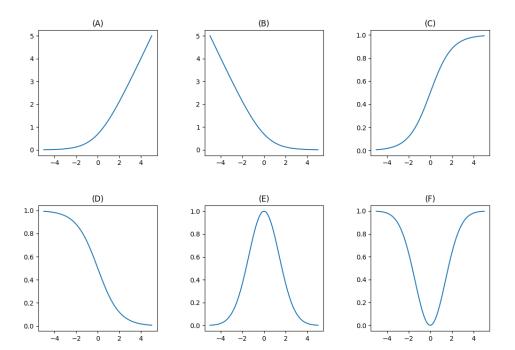

$$V = [0.5, 0.1, 0.4]$$

$$y = [0,7, 0.1, 0.4]$$

$$L) \qquad L(\eta) = \sum_{i} r_{i} l(\eta, y) = \sum_{i} r_{i}^{2} (1 - \rho_{i}) \stackrel{\frac{d}{d}r}{=} > 2 \sum_{i} r_{i} - 2 \sum_{i} r_{i} \rho_{i}$$

$$\sum_{i = 1}^{n} |\rho_{i} - y_{i}|$$

- 2. Consider a family of classification models with decision function  $H(x) = \text{sign}(F(x)), F : \mathbb{R}^d \to \mathbb{R}, H : \mathbb{R}^d \to \{-1,1\}$ . We will optimize the parameters  $\beta$  of function F by minimizing the expression  $\sum_i L(y_i \cdot F(x_i))$ . Explain your answers to the following questions.
- [6] (a) Which of the functions illustrated below can be used as a loss function L for the described classifier?
- [4] (b) Which loss function is the most rebust to outliers?
- [10] (c) Logistic regression is part of this familiy. What are the functions L and F which result in logistic regression? Which of the graphs corresponds to this loss function L? Help:  $p(y=1|\beta) = \sigma(z), \quad p(y=-1|\beta) = \sigma(-z).$

c) 
$$p(y|\beta) = \sigma(y \ge)$$

$$\sum_{i=y-i} x_i = \sum_{i=y-i} x_i = \sum_{i=$$

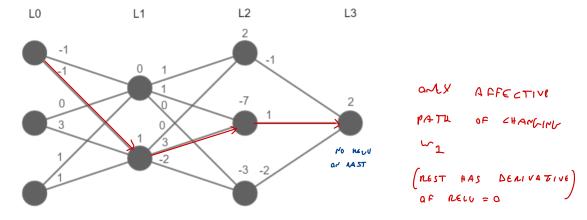

- 3. Derive an upper bound of the error rate  $(\epsilon_{NN})$  of a 1-nearest neighbor classifier in terms of the error rate  $(\epsilon_{OPT})$  of a Bayes optimal classifier as the number of instances approaches infinity  $(n \to \infty)$ . The class variable has m > 1 possible values.
- [4] (a) What is the prediction of a Bayes optimal classifier? What is its error rate?
- [8] (b) Show that  $\epsilon_{NN} \leq 2\epsilon_{OPT}$ .
- [8] (c) Prove a tighter bound  $\epsilon_{NN} \leq \epsilon_{OPT} (2 \frac{m}{m-1} \epsilon_{OPT})$ . Help: you might find the following form of the Cauchy–Schwarz inequality useful.

$$(\sum_{i=1}^{m} p_i)^2 \le m \sum_{i=1}^{m} p_i^2$$

$$\begin{array}{lll}

- 4. Given is a feed-forward neural network with two hidden layers (L1 and L2), input layer (L0), and output layer L3 (see figure). Let us denote the weighted sum of the inputs at layer i with vector  $z^{[i]}$  and activations with vector  $a^{[i]}$ . Let  $W^{[i]}_{jk}$  denote the weight connecting j-th unit of layer i-1 and k-th unit of layer i (illustrated above the lines).  $B^{[i]}_{j}$  denotes the bias of the j-th unit in layer i (illustrated above the nodes). All units use ReLU activation functions except for the output layer, which doesn't use an activation function.
- [6] (a) What is the output  $\hat{y}$  of the neural network for a data instance x = [2, 2, -1]?
- [14] (b) We aim to minimize the loss function  $J = \frac{1}{2} \sum_{i=1}^{m} (y_i \hat{y}_i)^2$ , where m indicates the number of data instances. Suppose we make one step of training (with learning rate 0.5) the illustrated network with a single data instance x = [2, 2, -1] that has a correct output y = 2. What is the new value of  $W_{0,1}^{[1]}$  (weight between the top unit of level 0 and the bottom unit of level 1) after this training step? Explain your calculation.

Hint: Think about which parts of the computation you can skip but don't forget to explain why.

$$\frac{dS}{d\omega_{1}} = \frac{dz_{1}}{d\omega_{1}} \cdot \frac{dz_{1}}{dz_{1}} \cdot \frac{dz_{2}}{dz_{1}} \cdot \frac{dz_{2}}{dz_{2}} \cdot \frac{dS}{dz_{2}} \cdot \frac{dS}{dz_{2}}$$

$$\frac{dS}{dz_{1}} = -1 \cdot (y - \hat{y}), \quad -(z - s) = 3$$

$$\frac{dS}{dz_{1}} = -1 \cdot (y - \hat{y}), \quad -(z - s) = 3$$

$$W_1 = W_1 - 4.5 \cdot 18 = -10$$

5. Bayesian statistics basics. Some help with distributions:

Bernoulli (pmf): 
$$P(x = k) = \begin{cases} 1 - p & \text{if } k = 0 \\ p & \text{if } k = 1 \end{cases}$$
,  $E[x] = p$ 

Beta (pdf): 
$$P(x) = \frac{x^{\alpha-1}(1-x)^{\beta-1}}{B(\alpha,\beta)}$$
,  $E[x] = \frac{\alpha}{\alpha+\beta}$ 

- [4] (a) Write Bayes' Theorem for the posterior  $p(\theta|y)$ , given likelihood  $p(y|\theta)$  and prior  $p(\theta)$ .
- [5] (b) Derive the posterior for  $\theta$  given n observations  $y = [y_1, \dots, y_n]$  if the likelihood is Bernoulli( $\theta$ ) and the prior is Beta( $\alpha, \beta$ ).
- [5] (c) Derive the definition of the posterior predictive p(y'|y) of a new observation y' given a set of n observations y. Express it with the likelihood and posterior only, explain the steps.
- [6] (d) Derive the posterior predictive for the Bernoulli-Beta case from above.
